Environmental Risk Assessment Data
Tamoxifen

Tamoxifen is a selective estrogen-receptor modulator (SERM), primarily indicated for the treatment of estrogen receptor positive breast cancer where it acts as an antiestrogen, preventing estrogen binding to the estrogen receptor.

Tamoxifen citrate is an active pharmaceutical ingredient used in the AstraZeneca product Nolvadex.

Tamoxifen citrate is rapidly metabolised by hydroxylation, demethylation and conjugation, giving rise to several metabolites which have a similar pharmacological profile to the parent compound and thus contribute to the therapeutic effect. The metabolites are excreted chiefly as conjugates in the bile, and little or no tamoxifen is eliminated as unchanged drug. Excretion is mainly via the faeces.

Tamoxifen citrate is not readily biodegradable. Once in the aquatic environment tamoxifen may be expected to adsorb to suspended solids and aquatic sediments.

Tamoxifen citrate is an ionisable compound. The octanol water distribution coefficients (Log Dow) values are <4.5 but >3. Predictive models show that that within the normal environmental pH range (pH 5 – 9) tamoxifen would not be expected to bioaccumulate. Furthermore, the work of Mills et al (Ref 1) shows that tamoxifen is likely to be readily metabolised in fish. Overall, the risk of bioaccumulation of tamoxifen in aquatic organisms is considered to be low.

The Predicted Environmental Concentration (PEC) / Predicted No Effect Concentration (PNEC) ratio is 0.47, which means use of tamoxifen is predicted to present a low risk to the environment.

Predicted Environmental Concentration (PEC)
The PEC is based on the following data:

PEC (µg/L) = (A*10^9*(100-R))/(365*P*V*D*100)

A (kg/year) = total patient consumption of tamoxifen citrate in the European country with the highest per capita use in 2016 (Source: IMS Health1)
R (%) = % removal during wastewater (sewage) treatment (due to loss by adsorption to sludge particles, by volatilisation, hydrolysis or biodegradation). It is assumed that R = 0 as a worst case.
P = number of inhabitants in the country with the highest per capita (Source: IMS Health2).
A/P = 2.6 x 10^-5 kg/inhabitant
V (L/day) = volume of wastewater per capita and day = 200 (European Medicines Agency (EMA) default value, Ref. 2)
D = factor for dilution of waste water by surface water flow = 10 (EMA default value)
(Note: The factor 10^9 in the equation above converts the quantity used from kg to µg)

PEC = 0.036 µg/L

(Note: Whilst tamoxifen is metabolised in the body, little is known about the ecotoxicity of the metabolites. Hence, as a worst case, for the purpose of this calculation, it is assumed that 100% of excreted metabolites have the same ecotoxicity as tamoxifen).

Predicted No Effect Concentration (PNEC)

The available aquatic toxicity data include studies undertaken using exposures to both tamoxifen citrate and tamoxifen base. Since the exposure assessment (PEC) is focused on the drug substance, tamoxifen citrate; toxicity values derived from tests performed with tamoxifen base have been adjusted to reflect the equivalent concentration of tamoxifen citrate. This was achieved by multiplying the No Observed Effect Concentration (NOEC) values by 1.517, based on the percentage of tamoxifen by molecular weight.

Long-term tests have been undertaken for species from three trophic levels, based on internationally accepted guidelines. The primary mode of action of tamoxifen is via estrogen receptor antagonism and therefore tamoxifen has potential modulate the reproductive endocrine axis. The potential for tamoxifen to effect reproduction in fish has been assessed in a reduced fish full life cycle test with fathead minnows and two further studies, reported in the scientific literature, have also assessed the effects on tamoxifen on reproduction in two other fish species. The PNEC is based on the lowest No Observed Effect Concentration (NOEC) 0.77 µg/L reported for zebra fish and an assessment factor of 10 is applied, in accordance with EMA guidance (Ref 2).

\[
PNEC = \frac{0.77 \, \mu g/L}{10} = 0.077 \, \mu g/L
\]

**PEC/PNEC**

\[
PEC = 0.036 \, \mu g/L \\
NPEC = 0.077 \, \mu g/L \\
PEC/PNEC = 0.47
\]

The PEC/PNEC ratio of 0.47 corresponds to the phrase ‘Use of tamoxifen has been considered to result in low environmental risk’ in the www.fass.se scheme (Ref 3).

Environmental Fate Summary

Tamoxifen citrate is not readily biodegradable. However, once in the aquatic environment tamoxifen citrate may be expected to adsorb to suspended solids and sediments.

Tamoxifen is ionisable and expected to be in its unionised (neutral) form at pH 9 and above; therefore, the ionized form is predicted to dominate in the aquatic environment. The octanol/water distribution coefficients suggest that that tamoxifen may have potential to bioaccumulate. However, Health Canada (Ref 4) modelled bioaccumulation potential using several different models and the results suggest that the Bioconcentration Factor (BCF) values for tamoxifen, and its metabolites, are expected to be below the classification threshold for bioaccumulative substances. In addition, the work of Mills et al (Ref 1) show that tamoxifen is expected to be extensively metabolised and excreted by fish and would not be expected to bioaccumulate. Overall, it is concluded that tamoxifen is unlikely to be bioaccumulative in aquatic organisms.
